## 2.33 Vertex Cover In Tree

```

#include <bits/stdc++.h>
using namespace std;
const int MAXN = 200010;
int dp[MAXN][2];
vector<int> adj[MAXN];
// vertexCover(node current, free to choose, dad)
int vertexCover(int u, bool color=true, int p=-1){
    if(dp[u][color] != -1)
        return dp[u][color];
    int case1 = 1, case2 = 0;
    for(int to: adj[u]){
        if(to == p) continue;
        case1 += vertexCover(to, true, u);
        case2 += vertexCover(to, false, u);
    }
    if(color)
        return dp[u][color] = min(case1, case2);
    else
        return dp[u][color] = case1;
}

```

## 3 Dynamic Programming

### 3.1 Alien Trick

```

#include <bits/stdc++.h>
#define F first
#define S second
using namespace std;
using ll = long long;
using pll = pair<ll, ll>;
pll solveDP(ll C);
ll solveMax(int k){
    ll lo = 0, hi=1e16, ans=1e16;
    while(lo <= hi){
        ll mid = (lo+hi)>>1;
        if(solveDP(mid).S <= k){
            ans = mid;
            hi = mid - 1;
        }else{
            lo = mid + 1;
        }
    }
    return solveDP(ans).F + k*ans;
}

```

### 3.2 Divide and Conquer Optimization

Reduces the complexity from  $O(n^2k)$  to  $O(nk \log n)$  of PD's in the following ways (and other variants):

$$dp[n][k] = \max_{0 \leq i < n} (dp[i][k-1] + C[i+1][n]), \text{ base case : } dp[0][j], dp[i][0] \quad (1)$$

- $C[i][j]$  = the cost only depends on  $i$  and  $j$ .
- $opt[n][k] = i$  is the optimal value that maximizes  $dp[n][k]$ .

It is necessary that  $opt$  is increasing along each column:  $opt[j][k] \leq opt[j+1][k]$ .

### 3.3 Divide and Conquer Optimization Implementation

```
#include <bits/stdc++.h>
using namespace std;
int C(int i, int j);
const int MAXN = 100010;
const int MAXK = 110;
const int INF = 0x3f3f3f3f;
int dp[MAXN][MAXK];
void calculateDP(int l, int r, int k, int opt_l, int opt_r){
    if (l > r)
        return;
    int mid = (l + r) >> 1;
    int ans = -INF, opt = mid;
    // int ans = dp[mid][k-1], opt=mid; //If you accept empty subsegment
    for (int i = opt_l; i <= min(opt_r, mid - 1); i++){
        if (ans < dp[i][k - 1] + C(i + 1, mid)){
            opt = i;
            ans = dp[i][k - 1] + C(i + 1, mid);
        }
    }
    dp[mid][k] = ans;
    calculateDP(l, mid - 1, k, opt_l, opt);
    calculateDP(mid + 1, r, k, opt, opt_r);
}
int solve(int n, int k){
    for (int i = 0; i <= n; i++)
        dp[i][0] = -INF;
    for (int j = 0; j <= k; j++)
        dp[0][j] = -INF;
    dp[0][0] = 0;
    for (int j = 1; j <= k; j++)
        calculateDP(1, n, j, 0, n - 1);
    return dp[n][k];
}
```

### 3.4 Knuth Optimization

Reduces the complexity from  $O(n^3)$  to  $O(n^2)$  of PD's in the following ways (and other variants):

$$dp[i][j] = C[i][j] + \min_{i < k < j} (dp[i][k] + dp[k][j]), \text{ caso base : } dp[i][i] \quad (2)$$

$$dp[i][j] = \min_{i < k < j} (dp[i][k] + C[i][k]), \text{ caso base : } dp[i][i] \quad (3)$$

- $C[i][j]$  = the cost only depends on  $i$  and  $j$ .
- $opt[i][j] = k$  is the optimal value that maximizes  $dp[i][j]$ .

The following conditions must be met:

- Foursquare inequality on  $C$ :  $C[a][c] + C[b][d] \leq C[a][d] + C[b][c]$ ,  $a \leq b \leq c \leq d$ .

- Monotonicity on  $C$ :  $C[b][c] \leq C[a][d]$ ,  $a \leq b \leq c \leq d$ .

Or the following condition:

- $opt$  increasing in rows and columns:  $opt[i][j-1] \leq opt[i][j] \leq opt[i+1][j]$ .

### 3.5 Knuth Optimization Implementation

```
#include <bits/stdc++.h>
using namespace std;
typedef long long ll;
const int MAXN = 1009;
const ll INFLL = 0x3f3f3f3f3f3f3f3f;
ll C(int a, int b);
ll dp[MAXN][MAXN];
int opt[MAXN][MAXN];
ll knuth(int n){
    for (int i = 0; i < n; i++){
        dp[i][i] = 0;
        opt[i][i] = i;
    }
    for (int s = 1; s < n; s++){
        for (int i = 0, j; (i + s) < n; i++){
            j = i + s;
            dp[i][j] = INFLL;
            for (int k = opt[i][j - 1]; k < min(j, opt[i + 1][j] + 1); k++){
                ll cur = dp[i][k] + dp[k + 1][j] + C(i, j);
                if (dp[i][j] > cur){
                    dp[i][j] = cur;
                    opt[i][j] = k;
                }
            }
        }
    }
    return dp[0][n - 1];
}
```

    int ans = 0;
    for(int x: v)
        ans ^= g[x];
    return ((ans != 0) ? "First" : "Second");
}

```

## 7.17 Simplex

```
#include <bits/stdc++.h>
using namespace std;
// Caution: long double can give TLE
typedef double ld;
typedef vector<ld> vd;
typedef vector<vd> vvd;
typedef vector<int> vi;
const ld EPS = 1e-9;

/*
 * Algorithm : Simplex ( Linear Programming )
 * Author : Simon Lo
 * Note: Simplex algorithm on augmented matrix a of dimension (m+1)x(n+1)
 * returns the result if feasible, -INF if not feasible, INF if unbounded
 * returns solution in b[] in original var order, max(f) in ret
 * n = number of variables (for i)
 * m = number of restrictions (for j)
 * form: maximize sum_i(c_i*x_i) s.t. for all j: sum_i(a_ij*x_i) <= b_j
 * in standard form.
 * To convert into standard form:
 * 1. for a>=b constraints, convert to -a<=-b
 * 2. if exists equality constraint, then replace by both >= and <=
 * 3. if variable x doesn't have nonnegativity constraint, then replace by
 * difference of 2 variables like x1-x2, where x1>=0, x2>=0
 * note: watch out for -0.0 in the solution, algorithm may cycle
 * EPS = 1e-7 may give wrong answer, 1e-10 is better
 */

/* Equations are of the matrix form Ax<=b, and we want to maximize
 * the function c. We are given coeffs of A, b and c. In case of minimizing,
 * we negate the coeffs of c and maximize it. Then the negative of returned
 * 'value' is the answer.
 * All the constraints should be in <= form. So we may need to negate the
 * coeffs.
 */

## 8 Theorems and Formulas

### 8.1 Binomial Coefficients

$$(a+b)^n = \binom{n}{0}a^n + \binom{n}{1}a^{n-1}b + \binom{n}{2}a^{n-2}b^2 + \dots + \binom{n}{k}a^{n-k}b^k + \dots + \binom{n}{n}b^n$$

Pascal's Triangle:  $\binom{n}{k} = \binom{n-1}{k-1} + \binom{n-1}{k}$

Symmetry rule:  $\binom{n}{k} = \binom{n}{n-k}$

Factoring in:  $\binom{n}{k} = \frac{n}{k} \binom{n-1}{k-1}$

Sum over  $k$ :  $\sum_{k=0}^n \binom{n}{k} = 2^n$

Sum over  $n$ :  $\sum_{m=0}^n \binom{m}{k} = \binom{n+1}{k+1}$

Sum over  $n$  and  $k$ :  $\sum_{k=0}^m \binom{n+k}{k} = \binom{n+m+1}{m}$

Sum of the squares:  $\binom{n}{0}^2 + \binom{n}{1}^2 + \dots + \binom{n}{n}^2 = \binom{2n}{n}$

Weighted sum:  $1\binom{n}{1} + 2\binom{n}{2} + \dots + n\binom{n}{n} = n2^{n-1}$

Connection with the Fibonacci numbers:  $\binom{n}{0} + \binom{n-1}{1} + \dots + \binom{n-k}{k} + \dots + \binom{0}{n} = F_{n+1}$

More formulas:  $\sum_{k=0}^m (-1)^k \cdot \binom{n}{k} = (-1)^m \cdot \binom{n-1}{m}$

### 8.2 Catalan Number

Recursive formula:  $C_0 = C_1 = 1$

$$C_n = \sum_{k=0}^{n-1} C_k C_{n-1-k}, n \geq 2$$

Analytical formula:  $C_n = \binom{2n}{n} - \binom{2n}{n-1} = \frac{1}{n+1} \binom{2n}{n}, n \geq 0$

The first few numbers Catalan numbers,  $C_n$  (starting from zero):  
1, 1, 2, 5, 14, 42, 132, 429, 1430, ...

The Catalan number  $C_n$  is the solution for:

- Number of correct bracket sequence consisting of  $n$  opening and  $n$  closing brackets.
- The number of rooted full binary trees with  $n+1$  leaves (vertices are not numbered). A rooted binary tree is full if every vertex has either two children or no children.
- The number of ways to completely parenthesize  $n+1$  factors.
- The number of triangulations of a convex polygon with  $n+2$  sides (i.e. the number of partitions of polygon into disjoint triangles by using the diagonals).
- The number of ways to connect the  $2n$  points on a circle to form  $n$  disjoint chords.
- The number of non-isomorphic full binary trees with  $n$  internal nodes (i.e. nodes having at least one son).

- The number of monotonic lattice paths from point  $(0,0)$  to point  $(n,n)$  in a square lattice of size  $n \times n$ , which do not pass above the main diagonal (i.e. connecting  $(0,0)$  to  $(n,n)$ ).
- Number of permutations of length  $n$  that can be stack sorted (i.e. it can be shown that the rearrangement is stack sorted if and only if there is no such index  $i < j < k$ , such that  $a_k < a_i < a_j$ ).
- The number of non-crossing partitions of a set of  $n$  elements.
- The number of ways to cover the ladder  $1 \dots n$  using  $n$  rectangles (The ladder consists of  $n$  columns, where  $i^{th}$  column has a height  $i$ ).

### 8.3 Euler's Totient

If  $p$  is a prime number:  $\phi(p) = p - 1$  and  $\phi(p^k) = p^k - p^{k-1}$

If  $a$  and  $b$  are relatively prime, then:  $\phi(ab) = \phi(a) \cdot \phi(b)$

In general:  $\phi(ab) = \phi(a) \cdot \phi(b) \cdot \frac{\gcd(a,b)}{\phi(\gcd(a,b))}$

This interesting property was established by Gauss:  $\sum_{d|n} \phi(d) = n$ , Here the sum is over all positive divisors  $d$  of  $n$ .

Euler's theorem:  $a^{\phi(m)} \equiv 1 \pmod{m}$ , if  $a$  and  $m$  are relatively prime.

Generalization:  $a^n \equiv a^{\phi(m) + [n \bmod \phi(m)]} \pmod{m}$ , for arbitrary  $a$ ,  $m$  and  $n \geq \log_2(m)$ .

### 8.4 Formulas

Count the number of ways to partition a set of  $n$  labelled objects into  $k$  nonempty labelled subsets.

$$f(n, k) = \sum_{i=0}^k (-1)^i \binom{k}{i} (k-i)^n$$

Stirling Number 2nd: Partitions of an  $n$  element set into  $k$  not-empty set. Or count the number of ways to partition a set of  $n$  labelled objects into  $k$  nonempty unlabelled subsets.

$$S_{2nd}(n, k) = \left\{ \begin{matrix} n \\ k \end{matrix} \right\} = \frac{1}{k!} \sum_{i=0}^k (-1)^i \binom{k}{i} (k-i)^n$$

Euler's formula:  $f = e - v + 2$

Euler's formula to  $n$  Lines or Segment if there is no three lines/segments that contains the same point:  $R = intersects + component - n$

Number of regions in a planar graph:  $R = E - V + C + 1$  where  $C$  is the number of connected components

Given  $a$  and  $b$  co-prime,  $n = a \cdot x + b \cdot y$  where  $x \geq 0$  and  $y \geq 0$ . You are required to find the least value of  $n$ , such that all currency values greater than

or equal to  $n$  can be made using any number of coins of denomination  $a$  and  $b$ :  
 $n = (a - 1) * (b - 1)$   
 generalization of the above problem,  $n$  is multiple of  $gcd(a, b)$ :  $n = lcm(a, b) - a - b + gcd(a, b)$

---

## 8.5 Manhattan Distance

Transformation of the manhattan distance to 2 dimensions between  $P_1 = (x_1, y_1)$  and  $P_2 = (x_2, y_2)$ :

$|x_1 - x_2| + |y_1 - y_2| = max(|A_1 - B_1|, |A_2 - B_2|)$  where  $A = (x_1 + y_1, x_1 - y_1)$  e  $B = (x_2 + y_2, x_2 - y_2)$

Transformation of the manhattan distance to 3 dimensions between  $P_1 = (x_1, y_1, z_1)$  and  $P_2 = (x_2, y_2, z_2)$ :

$|x_1 - x_2| + |y_1 - y_2| + |z_1 - z_2| = max(|A_1 - B_1|, |A_2 - B_2|, |A_3 - B_3|, |A_4 - B_4|)$  where  $A = (x_1 + y_1 + z_1, x_1 + y_1 - z_1, x_1 - y_1 + z_1, -x_1 + y_1 + z_1)$  e  $B = (x_2 + y_2 + z_2, x_2 + y_2 - z_2, x_2 - y_2 + z_2, -x_2 + y_2 + z_2)$

Transformation of the manhattan distance to D dimensions between  $P_1$  and  $P_2$ :

$isSet(i, x) = 1$  if the i-th bit is setted in  $x$  and 0 otherwise.

$$A[i] = \sum_{j=0}^{d-1} (-1)^{isSet(j,i)} P_1[j]$$

$$B[i] = \sum_{j=0}^{d-1} (-1)^{isSet(j,i)} P_2[j]$$

$$\sum_{i=0}^{d-1} |P_1[i] - P_2[i]| = \max_{i=0}^{2^d-1} |A_i - B_i|$$

---

## 8.6 Primes

If  $n = p_1^{e_1} \cdot p_2^{e_2} \cdot \dots \cdot p_k^{e_k}$ , then:

Number of divisors is  $d(n) = (e_1 + 1) \cdot (e_2 + 1) \cdot \dots \cdot (e_k + 1)$ .

Sum of divisors is  $\sigma(n) = \frac{p_1^{e_1+1}-1}{p_1-1} \cdot \frac{p_2^{e_2+1}-1}{p_2-1} \cdot \dots \cdot \frac{p_k^{e_k+1}-1}{p_k-1}$

---
